

In a **Book a Doctor Appointment System**, a **schema** defines the structure of data stored in the MongoDB database. Schemas are created using **Mongoose**, an Object Data Modeling (ODM) library for MongoDB. Each schema specifies the fields, data types, validation rules, and relationships for a particular collection. By using schemas, the application ensures that only valid and consistent data is stored in the database.

A **schema** is a blueprint or template that defines how data should be organized within a database collection. It specifies:

- Field names
- Data types
- Required fields
- Default values
- Validation rules
- Relationships with other collections

For example, a doctor schema defines details such as the doctor's name, specialization, qualifications, experience, consultation fee, and available timings.

Field	Description
Doctor Name	Full name
Specialization	Medical field
Qualification	Medical degrees
Experience	Years of experience
Consultation Fee	Appointment fee
Hospital Name	Hospital or clinic
Available Timings	Working hours
Rating	Average patient rating
Photo	Doctor profile image
